3.5. A particle of mass m slides over a rigid straight wire. The wire has one end fixed at the origin of the yz plane and rotates counterclockwise about the x axis. The particle is initially at a distance a from the origin and at rest with respect to the wire. Write the Lagrangian, find the equations of motion. Determine the equilibrium points and discuss their stability. Take as y-axis the axis initially containing the wire. Assume that the Earth's gravitational force is equal to $-mge_3$.

The Lagrangian is

$$L=T-V=\frac{1}{2}m(\vec{x}^{2}+\dot{y}^{2}+\dot{z}^{2})-mgz$$

$$=\frac{1}{2}m[(\dot{r}\cos\omega t-r\omega\sin\omega t)^{2}+(\dot{r}\sin\omega t+r\omega\cos\omega t)^{2}]-mgr\sin\omega t$$

$$=\frac{1}{2}m(\dot{r}^{2}+r^{2}\omega^{2})-mgr\sin\omega t$$

This gives the Euler-Lagrange equation

$$m\dot{r} - (mr\omega^2 - mg \sin \omega t) = 0 \iff \dot{r} - r\omega^2 = -g \sin \omega t$$

Its solution is

At to

$$\begin{array}{ccc}
\Upsilon(b) = \alpha \implies \alpha = A + B \\
\dot{\Upsilon}(b) = 0 \implies W(A - B) - \frac{4}{2W} = 0
\end{array}$$

$$\Rightarrow A = \frac{1}{2} \left(a + \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a + \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right) \implies A = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad B = \frac{1}{2} \left(a - \frac{4}{2W^2} \right), \quad$$

For large enough t r(t) > a, so the ball abandons the bar
